Figure 1: Protest for refugees

Abstract

view questions as proxies for attitude and knowledge and tested for coherence between the answers. Possible confounding factors such as age, gender and place were recorded and tested for significance. We find that people who oppose hosting more refugees tend to overestimate the real numbers whereas people who favor hosting more refugees tend to underestimate the real numbers. However, our data do not support a correlation between knowledge (i.e. precision of estimate) and attitude. While gender and age do not have a significant influence, answers differ significantly among the places where the interviews were conducted. In conclusion, our study shows that attitudes towards refugees depend more on their perceived presence rather than real knowledge about them.

1 Introduction

1.1 The broad topic and what has been done before

game theory hd game pd game pd hd and biology, processes in nature

The number of refugees asking for shelter in European Countries has strongly increased due to recent conflicts in the Near East and Africa. From 336,000 refugees applying for asylum in the EU in 2012, the number of applications has increased to 437,000 in 2013. Because the applications were not equally distributed among the different EU countries, some were not affected at all whereas others had to make enormous efforts to accommodate the refugees. Asylum applications in the UK (+4%) and France (+8%) only slightly increased in 2013, while for example Italy (+61%) and Germany (+64%) experienced a much stronger increase (?). In Germany as one of the main destination countries 127,000 refugees applied for asylum in 2013. 81,000 application were processed and only 20,000 refugees received a temporal or permanent residence permit (?). Now that many german municipalities struggle to find appropriate accommodation for the refugees, a public debate on whether or not to host more refugees has arisen. The opinions expressed differ largely among the population. While many people show honest empathy and try to help, there are many who do not want refugees living in proximity. Even utter xenophobia is pronounced occasionally. Media thereby often echo the most extreme positions.

In our perception the level of knowledge about refugees differs a lot among the population and the debate has turned very emotional so that it is often led by fear rather than facts. For this reason we want to investigate the public opinion and test whether people's attitudes are linked to their knowledge about refugees.

Previous Research:

There is a lot of research investigating the public opinion on immigrants, which can partly be transferred to the subgroup of refugees. Literature names several possible factors for negative attitudes towards asylum seekers. In general, the fear of crime and economic interests, such as the fear that migrants will take over all jobs have been identified as the most common reasons for negative attitudes towards refugees (?). Other authors focused on xenophobia and investigate whether it is related to gender (?) economics and education (?). Some studies have focused on the impact of media content on public opinion towards asylum seekers (???). Furthermore, many authors have investigated how personal experience or contact influences people's attitudes (?). ? describes the underlying psychological processes of prejudice. He established the highly regarded "Intergroup Contact Theory". Its basic message is that a lack of knowledge about a social group leads to prejudice which in turn makes people avoid that group - a self enforcing process. Only direct contact with the social group can refute people's prejudices and bring about higher levels of knowledge and acceptance. ? stresses the coherence between lack of knowledge and xenophobia: "From an objective point of view, these kinds of beliefs are mostly non-rational or irrational because of their inaccurate correspondence with reality. Put another way, they are mostly false".

1.2 Problem and Gap of Knowledge

A lot of researchers of social, economic or biological science worked on the evolutionary game theory.

Previous research suggests that people who know less about the number of refugees are less tolerant and less likely to approve of more refugees being accepted. However this debate has not come to a final conclusion yet. Authors like ? postulate that knowledge not necessarily correlates with what people think would be the right thing to do. We want to contribute to this discussion by investigating whether there peoples knowledge on refugees actually correlates with their support for Germany hosting more refugees.

1.3 Our approach and specific questions

Hypothesis:

In our study we test the following hypotheses:

- Spatial structure benefits cooperators especially in the Prisoner's Dilemma
- Neighborhood-size has an influence to the effect of spatial structure
- Mixed-strategies change the effect of spatial structure

For testing the Hypotheses we simulated different Hawk-Dove and Prisoners Dilemma games with NetLogo 5.1.0 and performed them with varying variables. The results of the experiments were fitted and visualized in R to make them comparable. The focus of the Experiments Data was set on the frequency of cooperators with different cost to benefit ratios.

Our experiments examined following questions:

- Which influence has spatial structure in the Hawk-Dove and Prisoners Dilemma game?
- Which effect have different neighborhood sizes to the games?
- Which influence has a mixed strategy of the players in a spatial and a nonspatial Hawk-Dove game?

2 Methods

2.1 Modeling environment

Data were collected in short interviews that were conducted at various locations in and around the city of Freiburg, Germany. The seven interview sites were the city center, the main station, the university campus, the "Vauban" residential district, a village called Denzlingen and a recreation area in the forest. These sites were selected to reflect a broad average of the Freiburg population. All data were collected on October 23rd, 2014 throughout the whole day to further maximize the variety in participants.

2.2 Effect of spatial structure in PD and HD games

Interview scheme Our data were collected by conducting short verbal questionnaires that include two main questions:

Question 1) Should Germany host more or less refugees?
Question 2) How many people were accepted as refugees in Germany in 2013?

- hallo gregor
- guten morgen

The term "refugees" includes asylum seekers, and the terms "to host" and "to be accepted" mean allowing them to stay in Germany either temporarily or permanently. To control for possible confounding factors, we additionally recorded the interviewees age, gender and nationality and any other applicable comments (see questionnaire in the appendix). Furthermore, we intentionally collected data from various participants (old, young, male, female, etc.). Before starting the interview we stated that the questionnaire is for a study conducted at the University of Freiburg.

Overall, a 165 people were interviewed. After excluding incomplete records and people not being german citizens 124 records remained. 86 out of them were in favor of hosting more refugees whereas 26 favored less refugees. 12 favored keeping the number stable. The lowest estimate for the number of refugees was 100 while the maximum estimate was 3,000,000.

2.3 Effect of neighbourhood size

Preparation: For data analysis we used the R statistics software package (?). For a preliminary evaluation of the data, we plotted some parameters and created a histogram of the estimate 2. Because of the highly skewed distribution of estimates we logarithmized the estimates to the base of 20,000 (i.e. the real number of refugees admitted) 3. The answers to Question 1 were numerified for analysis:

less refugees = -1
same number = 0
more refugees = 1

Regression: After preparing the data we applied two

linear regression models to the data. First, we checked for a correlation between the attitude records and the logarithmized absolute estimates. We then calculated the difference between the estimates and the real number of refugees and checked for a correlation between attitude records and the logarithmized absolute difference.

Confounding factors: In order to check whether one of the possible confounding factors had an influence on the attitude towards refugees, we conducted an analysis of variance for each of them.

Figure 3: Histograms of the logarithmized estimates

2.4 Effect of mixed strategies

3 Results

3.1 Effect of spatial structure in PD and HD games

In our first simulation experiment, we compared the effect of spatial structure on the persistence of cooperators in the PD and HD games.

(figure 4)

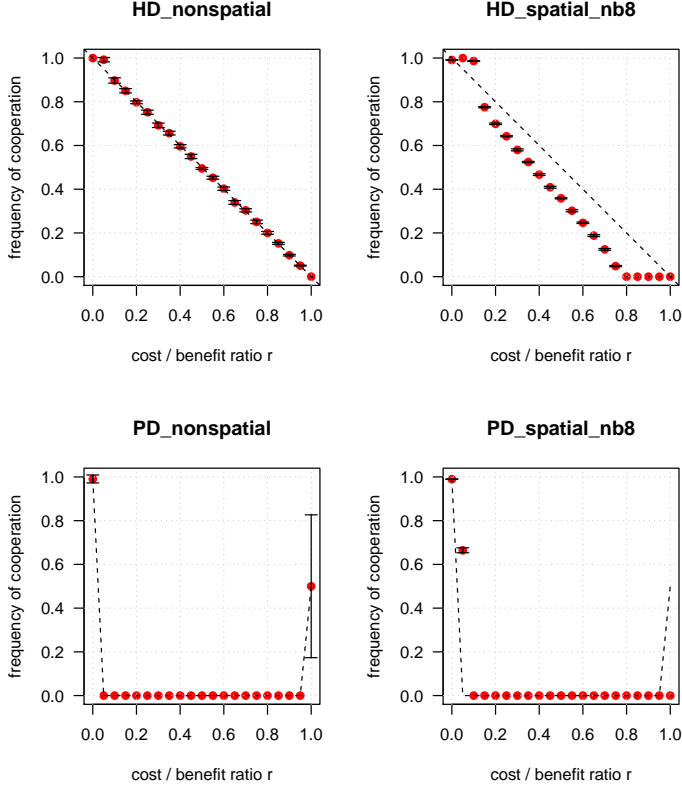

Figure 4: Comparison of HD and PD game simulations, both with and without spatial structure. [$t = 5000$, $i = 10$]

3.2 Effect of neighbourhood size

In the second simulation experiment we investigated the effect of

HD games

Figure 5: Effect of varying neighborhood size in the HD game. [$t = 5000$, $i = 10$]

PD games

Figure 6: Spatial PD game simulations with different neighbourhood sizes. [$t = 5000$, $i = 10$]

It is widely assumed that spatial structure allows for the evolution of cooperation in PD games. However, this goes only for a small range of cost-benefit ratios. Cooperation is only evolutionarily stable for r -values ≤ 0.09 , for bigger r -values it disappears from the population.

3.3 Effect of mixed strategies

4 Discussion and Conclusions

4.1 Main findings

spatial structure
different neighborhoods
mixed strategies

“What does cooperation mean in die Hawk-Dove game?”

4.2 Limitations

While gender and age do not have a significant influence on attitude, answers differ significantly among places where the interviews were conducted. We therefore assume that the selection of interview sites is relevant for the outcome. Due to the limited time and number of researchers in our study, our results can not be fully generalized. For reproducing our study on a large scale one should aim to select the interviewees as representative as possible.

Besides the selection of interview sites, the scheme of interviews might constitute a certain limitation to our study. As the interviews were conducted orally, the responses might be influenced by interactions between interviewer and interviewees. For example, interviewees might attribute a pro-refugee opinion to the interviewer and therefore not be honest when having a different opinion themselves. This goes especially for interviewers speaking English. Interviewees might assume that they are talking to migrants and might therefore not want to express a negative attitude towards refugees. Several times it occurred that interviewees were in company of other people who would try to influence the answers by making comments. Although we explicitly asked the interviewees for their personal opinion, the results may have been biased in some cases. To increase objectivity and avoid bias by personal interactions, one could switch to anonymized printed questionnaires in future studies.

4.3 Final conclusions, applications and further research

In conclusion, we found that people who oppose hosting more refugees tend to overestimate the real numbers whereas people who favor hosting more refugees tend to underestimate the real numbers. However, our data do not support a correlation between precision of estimate and attitude. We cannot tell from our data if this means that subtle perception rather than knowledge influences people’s attitude towards refugees. We therefore recommend further investigating this question with a more differentiated questionnaire that incorporates a well-defined proxy for the interviewees knowledge on refugees.

While gender and age did not significantly influence attitude in our study, answers differed significantly among places where the interviews were conducted. When reproducing this study, places for the interviews should be selected so that they represent an average of the population. Furthermore, we recommend using printed questionnaires to ensure objective and honest answers.

Acknowledgements

First of all we want to thank all participants of the interviews who have made the whole study possible. We also want to thank the R core team for their great statistics software. Sincere thanks are due to our teachers Dr. Florian Hartig and Paul Bauche for their competent support and advice. Special thanks go to Lisa Rubin for her helpful review of the manuscript.
